Sunspots are some of the most interesting, and longest studied, phenomena on the sun's surface. They were known to ancient Chinese observers over 2000 years ago. Below is a list of the largest sunspots seen since 1859 when careful measurements were first made of their sizes. Their sizes are given in terms of the area of the solar hemisphere facing earth. For example, '3600' means 3600 millionths of the solar area or ( $3600 / 1000000$ ). On this scale, the area of Earth is ' 169 '. All of these spots were large enough to be seen with the naked eye when proper (and safe!) viewing glasses were used.

## Years of Peak Sunspot Activity:

| Sunspot <br> Cycle | Peak <br> Year |
| :---: | :---: |
| 14 | 1906 |
| 15 | 1917 |

| 22 | 1989 |

Question 1: The peaks of the 11 -year sunspot cycle during the $20^{\text {th }}$ century occurred during the years shown to the left. On average, how close to sunspot maximum do the largest spots occur?

Question 2: From this sample, do more of these spots happen in the 5 years before sunspot maximum, or within 5 years after sunspot maximum?

Question 3: Convert the sunspot areas into an equivalent area of the Earth. (Note the first one has been done as an example). What is the average large spot size in terms of Earth?

Question 1: On average, how close to sunspot maximum do the largest spots occur? Answer: Find the average of the differences in last column = 0 years. So, the largest sunspots occur, on average, close to the peak of the sunspot cycle.

Question 2: For this sample, do more of these spots happen in the 5 years before sunspot maximum, or within 5 years after sunspot maximum? Answer: More happen after the peak. Five happen before the peak (negative differences) and 11 happen after the peak (Positive differences).

Question 3: What is the average large spot size in terms of Earth? Answer: Average $=(561.6 / 22)=25.5$ Earth Areas.
