

Seeing Solar Storms in STEREO - I

The two STEREO spacecraft are located along Earth's orbit and can view gas clouds ejected by the sun as they travel to Earth. From the geometry, astronomers can accurately determine their speeds, distances, shapes and other properties.

By studying the separate 'stereo' images, astronomers can determine the speed and direction of the cloud before it reaches Earth.

Use the diagram, (angles and distances not drawn to the same scale of the 'givens' below) to answer the following question.

The two STEREO satellites are located at points A and B, with Earth located at Point E and the sun located at Point S, which is the center of a circle with a radius ES of 1.0 Astronomical unit (150 million kilometers). Suppose that the two satellites spot a Coronal Mass Ejection (CME) cloud at Point C. Satellite A measures its angle from the sun mSAC as 45 degrees while Satellite B measures the corresponding angle to be mSBC=50 degrees. The CME is ejected from the sun at the angle mESC=14 degrees.

Problem 1 - The astronomers want to know the distance that the CME is from Earth, which is the length of the segment EC. They also want to know the approach angle, mSEC. Use either a scaled construction (easy: using compass, protractor and millimeter ruler) or geometric calculation (difficult: using trigonometric identities) to determine EC from the available data.

Givens from satellite orbits:

$$SB = SA = SE = 150 \text{ million km} \quad AE = 136 \text{ million km} \quad BE = 122 \text{ million km}$$

$$mASE = 54 \text{ degrees} \quad mBSE = 48 \text{ degrees}$$

$$mEAS = 63 \text{ degrees} \quad mEBS = 66 \text{ degrees} \quad mAEB = 129 \text{ degrees}$$

Find the measures of all of the angles and segment lengths in the above diagram rounded to the nearest integer.

Problem 2 - If the CME was traveling at 2 million km/hour, how long did it take to reach the distance indicated by the length of segment SC?

Answer Key

Givens from satellite orbits:

$SB = SA = SE = 150$ million km $AE = 136$ million km $BE = 122$ million km
 $mASE = 54$ degrees $mBSE = 48$ degrees
 $mEAS = 63$ degrees $mEBS = 66$ degrees $mAEB = 129$ degrees
 use units of megakilometers i.e. 150 million km = 150 Mkm.

Method 1: Students construct a scaled model of the diagram based on the angles and measures, then use a protractor to measure the missing angles, and from the scale of the figure (in millions of kilometers per millimeter) they can measure the required segments. **Segment EC is about 49 Mkm at an angle, mSEB of 28 degrees.**

Method 2 use the Law of Cosines and the Law of Sines to solve for the angles and segment lengths exactly.

$$mEAC = mEAS - mSAC = 63 - 45 = 18 \text{ degrees}$$

$$mASC = mASE + mESC = 54 + 14 = 68 \text{ degrees}$$

$$mASB = mASE + mBSE = 54 + 48 = 102 \text{ degrees}$$

$$mCSB = mASB - mASE - mESC = 102 - 54 - 14 = 34 \text{ degrees}$$

$$\text{SC from Law of Sines: } \frac{\sin(45)}{SC} = \frac{\sin(67)}{150} \text{ so } SC = 115 \text{ Mkm.}$$

$$\text{CB from Law of Cosines: } CB^2 = 115^2 + 150^2 - 2(115)(150)\cos(34) \text{ so } CB = 84 \text{ Mkm}$$

$$mEBC = mEBS - mSBC = 66 - 50 = 16 \text{ degrees}$$

$$\text{EC from law of Cosines: } EC^2 = 122^2 + 84^2 - 2(122)(84)\cos(16)$$

$$\text{EC} = 47 \text{ Mkm.}$$

$$\text{mCEB from Law of Cosines: } 84^2 = 122^2 + 47^2 - 2(122)(47)\cos(mCEB)$$

$$\text{mCEB} = 29 \text{ degrees}$$

$$\text{And since } mAES = 180 - mASE - mEAS = 180 - 54 - 63 = 63 \text{ degrees}$$

$$\text{so } mSEC = mAEB - mAES - mCEB = 129 - 63 - 29 = 37 \text{ degrees}$$

So, the two satellites are able to determine that the CME is 49 million kilometers from Earth and approaching at an angle of 37 degrees from the sun.

Problem 2 - If the CME was traveling at 2 million km/hour, how long did it take to reach the distance indicated by the length of segment SC?

Answer: 115 million kilometers / 2 million km/hr = **58 hours or 2.4 days.**
